

BUSINESS CASE STUDY

Customer Purchase Behaviour & Central Limit Theorem

By - Shivaling Battarki

Email: shivalingb09@gmail.com

About Walmart

Walmart is an American multinational retail corporation that operates a chain of supercenters, discount departmental stores, and grocery stores from the United States. Walmart has more than 100 million customers worldwide.

Business Problem

The Management team at Walmart Inc. wants to analyze the customer purchase behavior (specifically, purchase amount) against the customer's gender and the various other factors to help the business make better decisions. They want to understand if the spending habits differ between male and female customers: Do women spend more on Black Friday than men? (Assume 50 million customers are male and 50 million are female).

Dataset

The company collected the transactional data of customers who purchased products from the Walmart Stores during Black Friday. The dataset has the following features:

Dataset link: [Walmart_data.csv](#)

User_ID:	User ID
Product_ID:	Product ID
Gender:	Sex of User
Age:	Age in bins
Occupation:	Occupation(Masked)
City_Category:	Category of the City (A,B,C)
StayInCurrentCityYears:	Number of years stay in current city
Marital_Status:	Marital Status
ProductCategory:	Product Category (Masked)
Purchase:	Purchase Amount

Project Overview

This case study analyzes Walmart Black Friday transactional data to understand customer purchase behaviour and identify whether spending differs across gender, marital status, and age life stages.

Key Areas Covered

- Dataset structure, characteristics, categorical attributes, and statistical summary.
- Non-graphical and visual analysis of purchase behaviour and customer demographics.
- Missing-value and outlier detection.
- Comparison of male and female purchase behaviour and product-category mix.
- Central Limit Theorem and sampling distributions for different sample sizes.
- 90%, 95%, and 99% confidence intervals for population average spending.
- Comparison of spending between married and unmarried customers.
- Age-based analysis using the life stages: 0–17, 18–25, 26–35, 36–50, and 51+.
- Business insights, population-level interpretation, and actionable recommendations.

Based on the completed Jupyter / Google Colab analysis submitted in the following pages.

Walmart Business Case Study: Customer Purchase Behavior & Central Limit Theorem Analysis

Executive Summary & Business Context

Walmart Inc. is an American multinational retail corporation operating a chain of hypermarkets, discount departmental stores, and grocery stores. With over 100 million customers worldwide, understanding consumer spending dynamics during peak promotional events—especially **Black Friday**—is paramount for strategic decision-making, inventory allocation, pricing, and personalized marketing.

Core Business Problem

The Management team at Walmart Inc. wants to analyze customer purchase behavior (specifically, **purchase amount**) against customer demographics (**Gender, Age, Marital Status, City Category, Stay in City, and Occupation**) to answer fundamental business questions:

1. **Do women spend more on Black Friday than men?** (Assuming a total population of **50 million male** and **50 million female** customers).
2. **What are the Confidence Intervals for average male and female spending?** Do they overlap, and what are the strategic implications for Walmart?
3. **How does spending vary across Marital Status (Married vs Unmarried)?**
4. **How does spending evolve across Age Life Stages (0-17 , 18-25 , 26-35 , 36-50 , 51+)?**
5. **How can the Central Limit Theorem (CLT) be leveraged to make reliable population-level inferences from transactional sample data?**

17
18
```

```
==== Outlier Analysis on Purchase Amount ====
Q1 (25th percentile):    $5823.00
Q3 (75th percentile):    $12054.00
IQR:                     $6231.00
Lower Threshold:         $-3523.50
Upper Threshold:         $21400.50
Outliers:                2677, records 0.49% of total data
```

Key Observations

1. Zero Missing Values: The dataset is clean across all 550,068 rows with no missing entries.
2. Customer vs Product Scope: There are **5,891 unique customers** purchasing **3,631 distinct products** across 550,068 transactions.
3. Demographics:
 - Gender: Transactions are 75.3% Male (414,259 transactions) and 24.7% Female (135,809 transactions).
 - Age: The customers in life stage 26–35 age group dominate sales volume (39.9%), followed by 36–45 (20.0%) and 18–25 (18.1%).
 - City Category: City B accounts for 42.0% of transactions, City C for 31.1%, and City A for 26.8%.
 - Marital Status: 59.0% of customers are by unmarried individuals and 41.0% by married individuals.
4. Outlier Interpretation:
 - The IQR rule identifies 2,677 transactions (> \$21,400.50) as statistical outliers (only 0.49% of data).
 - Business Decision: These purchases represent genuine high-ticket transactions (such as major electronics, televisions, appliances) typical during Black Friday doorbuster sales. *They must NOT be removed*, as retaining them is essential for accurate revenue modeling and inventory valuation.

3. Visual Analysis (Univariate, Bivariate)

In this section, we visually explore distributions, demographic patterns, relationships between features, and correlations.

Insights from Visual Analysis

- Purchase Distribution:** The purchase histogram displays peaks around amounts 5000, 8000, 12000, 15000, and 19000-20000. These correspond to distinct standardized retail price tiers (e.g. entry accessories, mid-range appliances, premium electronics).
- Gender Spend Difference:** Male Customer transactions exhibit a higher upper quartile and higher median spend compared to female customer transactions.
- Marital Status Invariance:** The purchase distributions for married vs unmarried customers are identical across quartiles, medians, and spreads.
- Age Groups:** Average spend increases steadily across the life stages, with customers aged 51+ exhibiting the highest median spend.
- Low Linear Correlation:** Correlation between attributes and individual transaction amounts are ($|r| < 0.1$), indicating that transaction spending is governed by non-linear categorical preferences and basket selection rather than simple monotonic linear relationships. The closest to near linear correlatin is between Product Category and Purchase ($r = -0.34$), although a *-ve* correlation.

4. Answering Core Questions

Question 1: Are women spending more money per transaction than men? Why or why not?

To address this question with mathematical rigor, we analyze the metrics at two fundamental levels:

- Transaction Level:** Amount spent per individual transaction.
- Customer Level:** Total spending, transaction count, and average spend per individual user.
- Product Category Mix**

1

```
1 # 4.1 Transaction-Level Metrics by Gender
2 gender_tx_summary = walmart.groupby('Gender', observed=False)['Purchase'].agg(
3     Transaction_Count='count',
4     Mean_Spend='mean',
5     Std_Dev='std',
6     Median_Spend='median'
7 ).reset_index()
8
```

```

9 gender_tx_summary['Share_of_Transactions_%'] = (gender_tx_summary['Transaction_Count'] / len(walmart)) * 100
10 print("==== Transaction-Level Summary by Gender ====")
11 display(gender_tx_summary)
12 print('\n')
13
14 # 4.2 Customer-Level Metrics by Gender
15 user_agg = walmart.groupby(['User_ID', 'Gender'], observed=False).agg(
16     Total_Spend=('Purchase', 'sum'),
17     Transaction_Count=('Purchase', 'count'),
18     Avg_Spend_Per_Tx=('Purchase', 'mean')
19 ).reset_index()
20 # print(user_agg, end='\n')
21 # print('\n')
22
23 user_summary = user_agg.groupby('Gender', observed=False).agg(
24     Customer_Count=('User_ID', 'count'),
25     Mean_Total_Spend=('Total_Spend', 'mean'),
26     Median_Total_Spend=('Total_Spend', 'median'),
27     Mean_Tx_Count=('Transaction_Count', 'mean'),
28     Mean_Avg_Spend_Per_Tx=('Avg_Spend_Per_Tx', 'mean')
29 ).reset_index()

```

Answer to Question 1: Do Women Spend More Than Men?

Conclusion: NO. Women do NOT spend more money per transaction than men.

- Per Transaction: Men spend an average of \$9,437.53, whereas women spend an average of \$8,734.57. Male spend is higher by \$702.96 per transaction (+8.05%).
- Per Customer: Male customers generate an average total spend of \$925,344 across 98.0 transactions, whereas female customers generate \$712,024 across 81.5 transactions.

Why do men spend more?

1. Equal Purchasing Power Within Categories: When we inspect individual product categories, men and women spend virtually identical amounts:
 - In Product Category 1: Women spend \$13,597.16 vs Men \$13,608.16 (difference of only \$11.00).
 - In Product Category 5: Women spend \$6,307.24 vs Men \$6,214.23 (women actually spend \$93 more).
 - In Product Category 8: Women spend \$7,499.92 vs Men \$7,498.55 (difference of \$1.37).
2. The Product Mix Shift:
 - Men allocate 27.89% of all their purchases to Product Category 1 (items averaging \$13,600+), compared to only 18.28% for women.
 - Women allocate a higher share of their transactions to lower-ticket categories like Category 5 (30.90% for women vs 26.31% for men).
 - Therefore, the higher overall spending of men is driven entirely by product selection mix, not because men pay more for the same goods.

1

Question 2: How does sample size affect the distribution of mean expenses for male and female customers?

Question 3: Are confidence intervals of average male and female spending overlapping? How can Walmart leverage this conclusion?

5. Confidence Interval & Central Limit Theorem

The dataset represents a sample of Walmart transactions. We use this sample to estimate the average purchase amount for the larger male and female customer populations.

We first calculate Confidence Intervals for male and female customers and then use different sample sizes to understand how the distribution of sample means changes.

```
1 # 5.1 95% Confidence Interval for Purchase Amount by Gender
2
3 ci_results = []
4
5 for gender in ['F', 'M']:
6     sample = walmart[walmart['Gender'] == gender]['Purchase']
```

```

7     sample_mean = sample.mean()
8     sample_std = sample.std()
9     sample_size = len(sample)
10    standard_error = sample_std / np.sqrt(sample_size)
11    ci = stats.norm.interval(confidence=0.95, loc=sample_mean, scale=standard_error)
12
13    ci_results.append([gender, sample_size, sample_mean, ci[0], ci[1]])
14
15 ci_df = pd.DataFrame(ci_results, columns=[
16     'Gender',
17     'Sample Size',
18     'Mean Purchase',
19     '95% CI Lower',
20     '95% CI Upper'
21 ])
22 )
23
24 display(ci_df)

```

	Gender	Sample Size	Mean Purchase	95% CI Lower	95% CI Upper
0	F	135809	8734.566	8709.212	8759.920
1	M	414259	9437.526	9422.019	9453.033

Next steps: [New interactive sheet](#)

5.2 Central Limit Theorem — Effect of Sample Size

To understand how sample size affects the sample mean, we take repeated random samples of different sizes and calculate the mean purchase amount for each sample.

Sample sizes used:

- 30
- 100
- 500
- 1000

We repeat the sampling process 1,000 times for each sample size.

```

1 # 5.3 CLT - Female Customers
2
3 sample_sizes = [30, 100, 500, 1000]
4 number_of_samples = 1000
5

5	M	99.000	9417.147	9457.905

Next steps: [New interactive sheet](#)

Observations

1. The 90% confidence interval is the narrowest.
2. The 95% confidence interval is wider than the 90% interval.
3. The 99% confidence interval is the widest.
4. As the confidence level increases, the confidence interval becomes wider.
5. This means that a higher level of confidence requires a wider range around the sample average.

5.7 95% Confidence Interval - Male vs Female

We calculate the 95% confidence interval for the average purchase amount of Male and Female customers and compare the intervals to understand whether their average spending is clearly different.

```

```

Business Conclusion on Confidence Intervals & Overlap:

1. Zero Overlap at All Confidence Levels:

- Even at the most conservative 99% Confidence Level, the Female interval is [\$8,701.24, \$8,767.89] while the Male interval is [\$9,417.15, \$9,457.90].
- The gap between the upper bound of female spend and the lower bound of male spend is \$649.26.

2. How Walmart Can Leverage This Conclusion:

- Targeted Black Friday Campaigns: Since men spend more per transaction and represent 75.3% of transaction volume, Walmart should maintain aggressive marketing and doorbuster positioning for high-ticket male-leaning categories (electronics, gaming, tools).
- Upselling & Basket Building for Women: Since women have equal spending within categories but lower overall transaction size due to lower-ticket category preference, Walmart should deploy cross-category bundling (e.g. bundling high-margin electronics with lifestyle/apparel items) to elevate female basket sizes.
- Inventory Allocation: Allocate prime floor space and warehouse safety stock in higher proportion to high-ticket Category 1 goods to meet heavy male demand without stockouts.

Question 4: Does purchase behavior differ significantly between Married and Unmarried customers?

6. Demographic Deep-Dive: Married vs Unmarried

We apply the exact same CLT and Confidence Interval methodology to compare **Unmarried** (`Marital_Status = 0`) and **Married** (`Marital_Status = 1`) customers across 90%, 95%, and 99% confidence levels.

```
1 walmart['Marital_Status'].head(2)
```

Marital_Status

0	Unmarried
1	Unmarried

dtype: category

```

Findings for Married vs Unmarried Customers

1. Negligible Spend Difference: Unmarried customers spend an average of \$9,265.91 while married customers spend \$9,261.17. The difference is a mere \$4.74 per transaction.
2. Confidence Intervals Overlap Completely:
 - At 95% Confidence: Unmarried [\$9,248.62, \$9,283.20] vs Married [\$9,240.46, \$9,281.88].
 - At 99% Confidence: Unmarried [\$9,243.18, \$9,288.63] vs Married [\$9,233.95, \$9,288.40].
3. Actionable Business Takeaway: Walmart should NOT segment pricing, promotional discounting, or general catalog curation based on marital status. Budget allocation should not be wasted on tailoring separate Black Friday pricing tiers for married vs single shoppers.

Question 5: How does purchase amount vary across customer life stages?

7. Demographic Deep-Dive: Age Life Stages

We categorize age into the 5 business life stages:

- **0-17** : Minors / Teens (Dependent)
- **18-25** : Young Adults / College / Entry-level
- **26-35** : Prime Working Age / Early Career
- **36-50** : Mature Professionals / Families
- **51+** : Empty Nesters & Seniors (Peak Disposable Income)

We compute descriptive metrics, sampling distributions, 90%/95%/99% Confidence Intervals.

```

1 # Purchase Summary - Age Life Stages

Findings across Age Life Stages

1. Monotonic Spending Gradient:

- 0-17 : \$8,933.46 (Lowest spend per transaction; young dependents with limited budgets).
- 18-25 : \$9,169.66
- 26-35 : \$9,252.69 (Highest transaction volume: 219,587 transactions, 39.9% of total store activity).
- 36-50 : \$9,295.33
- 51+ : \$9,463.66 (Highest spend per transaction; established financial wealth and premium basket preference).

2. Overlap Dynamics:

- The 51+ cohort's 95% CI [\$9,423.17, \$9,504.16] does NOT overlap with 26-35 , 18-25 , or 0-17 .
- The 0-17 cohort's 95% CI [\$8,851.95, \$9,014.98] is strictly detached below all other age brackets.
- The intermediate adult brackets (26-35 and 36-50) exhibit adjacent, slightly overlapping intervals.

8. Final Insights & Generalization to Population

Extrapolating to the 100 Million Customer Base (50M Male, 50M Female)

Assuming Walmart has 50 million male and 50 million female customers globally:

Metric	Female Population (50M)	Male Population (50M)	Total Projected Market
Point Estimate Spend / Transaction	\$8,734.57	\$9,437.53	\$9,263.97 (weighted)
95% Confidence Interval	[\$8,709.21, \$8,759.92]	[\$9,422.02, \$9,453.03]	Non-Overlapping
Average Transactions / Customer	~81.5 transactions	~98.0 transactions	~93.4 transactions
Annualized Total Customer Spend	~\$712,024	~\$925,344	~\$865,000
Top Volume Driver Category	Category 5 (Apparel/Home)	Category 1 (Electronics/Appliances)	Category 1 & 5
Geographic Epicenter	City B & City C	City B & City C	City B (Tier-2 Powerhouse)

• **The True Differentiator:** It is **not** marital status, and **not** city residency duration. The two primary drivers of Black Friday basket revenue are:

1. **Gender-Driven Category Mix Shift:** High-ticket Category 1 vs standard retail goods.
2. **Age Life Stage Capitalization:** Senior shoppers (51+) having higher average purchasing power.

9. Actionable Business Recommendations for Walmart Management

1. Bundle High-Margin Electronics with Lifestyle Products for Female Shoppers

- **Action:** Women spend the same dollar amount as men when buying Category 1 items, but buy them less frequently. Create curated Black Friday bundles—e.g. smart home assistants, premium headphones, or fitness trackers packaged with popular apparel or home goods at an attractive package discount.
- **Goal:** Elevate female transaction size toward the \$9,400+ mark.

2. Safeguard High-Ticket Inventory (Product Category 1) for Peak Male Shoppers

- **Action:** Men account for 75.3% of transactions and 27.9% of their purchases are in high-ticket Category 1.
- **Goal:** Implement dynamic inventory pre-allocation to prevent out-of-stock events on top-selling SKUs in Category 1, particularly in City B stores.

3. VIP Fast-Track & Premium Curation for Senior Shoppers (Ages 51+)

- **Action:** Shoppers aged 51+ have the highest average spend per purchase (\$9,463.66). Offer early-access digital shopping hours, premium home delivery, and dedicated concierge customer service during Black Friday.
- **Goal:** Maximize high-margin, high-ticket conversions for your most affluent customer cohort.

4. Eliminate Ineffective Marital-Status Segmentation

- **Action:** Married and unmarried customers spend virtually identical amounts (\$9,261 vs \$9,265).
- **Goal:** Consolidate marketing campaigns and stop allocating creative or media spend toward separate single vs married promotions. Reallocate those marketing dollars toward category-specific campaigns.

5. Expand Fulfillment & Local Merchandising in City Category B

- **Action:** City B generates 42% of total transaction volume and exhibits consistent high average transaction sizes.
- **Goal:** Expand regional fulfillment micro-hubs and prioritize inventory replenishment runs to City B distribution centers ahead of the holiday rush.
